

Small documentation notes •

Hi Roland, hi Peter,

While implementing Parigo from the Public API documentation, I noted the small discrepancies below. For each functional issue, I have included the syntax that worked for me.

01 addtrackmembercomment

DOCUMENTED

```
{ "TrackID": "<track-id>", "TagName": "Comment" }
```

WORKED

```
{ "trackid": "<track-id>", "TagName": "Comment" }
```

The track ID property is case-sensitive. TrackID returned Error.Code=2: trackid is empty.

02 updatetrackmembercomment

DOCUMENTED

```
{ "TrackID": "<comment-id>", "TagName": "Updated" }
```

WORKED

```
{ "TagID": "<comment-id>", "TagName": "Updated" }
```

The value is the comment/tag ID, not the track ID. TagID and tagid both persisted successfully.

03 getmembertoken response

The JSON example uses Token and PersistentLoginToken.Value, and contains a trailing comma.

Live response: MemberToken + PersistentLoginToken.Token

04 gettoptracks request

The JSON example contains an inline // comment after TrackType, so it does not parse as JSON. Removing the comment makes the documented payload valid and it works.

05 getcuesheet response

The sample URL contains one extra closing brace: `https://{cuesheetdomainpath}}/afile.csv`. The live endpoint returns a valid URL.

These notes are not intended as a full audit - they are simply the issues I encountered while implementing. The comment create/update alternatives above were confirmed live, and the test comments were removed afterwards.
